21 **Abstract**

22
23 Stem cell factor (SCF) and its receptor c-kit have been implicated in inflammation, tissue
24 remodeling, and fibrosis. Ingenuity® Integrated Pathway Analysis (IPA) of gene expression array
25 datasets showed an upregulation of SCF transcripts in IPF lung biopsies compared to tissue
26 from non-fibrotic lungs that are further increased in rapid progressive disease. SCF248, a
27 cleavable isoform of SCF, was abundantly and preferentially expressed in human lung
28 fibroblasts and fibrotic mouse lungs relative to the SCF220 isoform. In fibroblast-mast cell co-
29 culture studies, blockade of SCF248 using a novel isoform specific anti-SCF248 monoclonal
30 antibody (anti-SCF248), attenuated the expression of *COL1A1*, *COL3A1* and *FN1* transcripts in
31 *co-cultured IPF but not normal lung fibroblasts*. Administration of anti-SCF248 on days 8 and 12
32 after bleomycin instillation in mice significantly reduced fibrotic lung remodeling and *col1a1*, *fn1*,
33 *acta2*, *tgfb* and *ccl2* transcript expression. In addition, bleomycin increased numbers of c-kit+
34 mast cells, eosinophils, and ILC2 in lungs of mice, whereas they were not significantly increased
35 in anti-SCF248 treated animals. Finally, mesenchymal cell specific deletion of SCF significantly
36 attenuated bleomycin-mediated lung fibrosis and associated fibrotic gene expression.
37 Collectively, these data demonstrate that SCF is upregulated in diseased IPF lungs and
38 blocking SCF248 isoform significantly ameliorates fibrotic lung remodeling *in vivo*, suggesting
39 that it may be a therapeutic target for fibrotic lung diseases.

40

41

42 Introduction

43 With a high global prevalence, chronic diseases often have severe complications,
44 including end-stage tissue fibrosis that can ultimately culminate in organ/tissue dysfunction.
45 Chronic fibrotic diseases, such as idiopathic pulmonary fibrosis (IPF), have been challenging to
46 treat clinically, where many affected patients eventually require organ transplantation or
47 succumb to the disease(9, 25, 43, 67). While many pro-fibrotic mediators have been identified,
48 therapeutically targeting many of these mediators have failed to modulate fibrotic progression
49 and promote tissue regeneration(54, 57). Recently, nintedanib (OFEV[®]) and pirfenidone
50 (Esibret[®]) have been FDA approved for the treatment of IPF patients(23, 39, 46, 59, 60). These
51 drugs have significant side effects and were only effective in slowing down, but not halting,
52 disease progression. Thus, great effort is underway to develop next generation therapeutics
53 that are more effective at halting the fibrotic remodeling of the lung and promoting lung
54 regeneration.

55 Fibrotic diseases have been often observed to have a strong inflammatory component,
56 suggesting a role of inflammation in tissue fibrosis. Indeed, there is evidence for inflammatory
57 processes and/or inflammatory cell infiltrates in fibrotic tissues, including the lung(30, 32, 50),
58 kidney(48) and liver(61). While the role of inflammation in lung injury and disrepair in IPF
59 remains controversial, clinical evidence suggests a correlation between inflammatory infiltrates
60 and disease progression(4) and pre-clinical studies suggest that targeting inflammatory
61 responses may ameliorate fibrotic lung remodeling (10, 29, 38, 56). However,
62 immunosuppressive therapies have failed to modulate IPF disease progression clinically(33),
63 suggesting that targeting profibrotic mechanisms may also be required to modulate clinical
64 disease progression. Stem Cell Factor (SCF) is a cytokine involved in hematopoietic cell
65 development of multiple lineages as well as mast cell differentiation and activation (24, 47).
66 SCF binds to its surface receptor, c-Kit, which is a member of the receptor tyrosine kinase
67 family (3, 24). Studies targeting c-kit activation using receptor tyrosine kinase inhibitors, imatinib
68 or nilotinib, have shown promising results in animal models but have not shown similar

69 outcomes in an initial study in IPF using a non-selective patient population (2, 12, 58, 69). Since
70 c-kit inhibitors have broad effects on homeostatic function (as well as the off-target RTKs
71 inhibited), a specific and refined approach such as targeting the ligand may be more effective.
72 Endogenous SCF occurs primarily in 2 forms, a 248 amino acid (AA) cleavable form (SCF248)
73 and a 220 AA "non-cleavable" form (SCF220) that differ by the presence or absence of exon 6
74 that encodes for protease cleavage site(s). Both isoforms of SCF are inserted into the plasma
75 membrane, with the extracellular domain (ECD) of SCF248 more efficiently cleaved and shed
76 from the surface of the cell during inflammation. While SCF-ECD is abundantly detected in
77 circulation (~800 pg/ml in humans), circulating SCF-ECD is primarily monomeric that cannot
78 crosslink and activate c-kit (31). Thus, c-kit activation is thought to primarily occur through the
79 membrane-associated forms of SCF, which can efficiently crosslink the receptor leading to its
80 phosphorylation and activation (13) (49).

81 The physiological roles of membrane-associated SCF were determined using SI/Sld
82 mice (lacking both forms of membrane associated SCF) that are runted, anemic, and have
83 altered myelopoiesis and inflammatory/immune responses. A fundamental study examined
84 whether the 2 splice variants of SCF have differential biologic effects using SI/Sld mutant mice
85 embryonically transfected with either SCF248 or SCF220. The phenotype observed in these
86 mice suggests an important and non-redundant role of SCF220 in development and
87 erythropoiesis, as its expression corrected the defects. However, SCF248 expression in these
88 mice promoted normal myelopoiesis with little effect on runting and anemic phenotypes of SI/Sld
89 mice, suggesting that the SCF248 isoform of SCF may be associated with myelopoiesis and the
90 propagation of inflammation responses (36). Finally, the role of the SCF variant, SCF220, was
91 confirmed in another study examining mice expressing SCF220 (but not SCF248) isoform.
92 These mice were observed to develop normally (with no runting or anemia); however, there was
93 a notable alteration in myelopoiesis and an absence of mast cells (65). Together, these studies
94 suggest that SCF isoforms may play divergent roles in development, erythropoiesis and
95 myelopoiesis, where SCF220 may be required during development and erythropoiesis and

96 SCF248 may be required for normal myelopoiesis and mast cell development and/or
97 differentiation.

98 In the present study, we show evidence that *KITLG* expression (gene name for SCF)
99 and protein are elevated in IPF. Further, SCF248 is preferentially and significantly elevated in
100 human lung fibroblasts. Targeting this isoform using anti-SCF248 specific antibodies
101 significantly reduced *COL1A1*, *COL3A1* and *FN1* transcript expression in IPF, but not normal
102 lung fibroblasts, co-cultured with mast cells. SCF248, but not SCF220, was markedly
103 upregulated in fibrotic murine lungs and targeting SCF248 with specific antibodies significantly
104 ameliorated bleomycin induced lung fibrosis and profibrotic transcript expression. Finally,
105 mesenchymal cell specific deletion of SCF significantly ameliorated bleomycin mediated lung
106 remodeling. Collectively, our results suggest that the ability to target the SCF248 isoform, that
107 is upregulated during fibrotic pulmonary diseases (including IPF), may be central to preserve
108 important homeostatic functions of SCF (such as erythropoiesis) while blocking the detrimental
109 pro-fibrotic effects of c-Kit⁺ cell activation.

110

111

112 **Results**

113 Expression of SCF in pulmonary disease.

114 Our previous studies using a bleomycin model of pulmonary fibrosis demonstrated that
115 therapeutically blocking SCF in the remodeling phase attenuated the development of
116 fibrosis(15). To assess potential role(s) of these proteins in clinical IPF, publicly available
117 datasets (GSE10667) from IPF, exacerbated IPF, and non-diseased lungs were analyzed using
118 Ingenuity IPA. As shown in Figures 1A-B, Ingenuity upstream regulatory analyses, which
119 indicate the activation of genes (orange/red), predicted enhanced activation of *KITLG* (SCF) in
120 IPF relative to normal (Figure 1A) and SCF was further increased in exacerbated IPF relative to
121 stable IPF lungs (Figure 1B). Upregulated *KITLG* downstream mediators identified by this
122 analysis included pro-survival and pro-inflammatory transcripts several of which have been
123 identified as potential therapeutic targets. Consistent with Ingenuity's analyses, there was a
124 significant increase in SCF protein in IPF patients' serum samples relative to normal donor
125 serum controls (Figure 1C). These data support findings from previous reports(15, 72) and
126 illustrate that SCF (*KITLG*) is upregulated in IPF patients and may play a role in IPF disease.

127 SCF248 is upregulated in IPF patient derived fibroblasts and in bleomycin-induced pulmonary
128 fibrosis. When the expression of both SCF isoforms was examined, SCF248 was present in
129 lung fibroblasts from both normal and IPF patients at higher levels (10 to 20-fold) than SCF220
130 with increased SCF248 significantly higher (P=0.02) in IPF patient derived fibroblasts (Figure
131 2A). We also examined the differential expression of SCF isoforms during bleomycin induced
132 lung fibrosis in mice and found that the primary SCF isoform induced is SCF248, with little or no
133 increase in SCF220 (Figure 2B). Together these results suggest that SCF248 is highly
134 expressed in fibroblasts from lungs of patients and during pulmonary fibrosis and that fibroblast-
135 derived SCF248 is preferentially expressed in fibrotic mouse lungs. These results are
136 consistent with our recent publication in chronic allergen-induced asthma indicating that
137 SCF248 is highly upregulated in chronic remodeling disease(21) and supports the preferential
138 expression of SCF248 over SCF220 in fibroblasts.

139 Characterization of mAb to SCF248 –

140 Our results suggest that SCF248 is the predominant SCF isoform expressed in the
141 fibrotic lungs of bleomycin treated mice and in fibroblasts from IPF patients. Thus, a
142 sophisticated targeting strategy was pursued to make mAb against the portion of SCF that
143 differentiates SCF248 from SCF220 as complete loss of SCF/c-kit signaling has adverse effects
144 on developmental pathways and erythropoiesis. *MAb* were generated against a peptide found in
145 exon 6 of SCF248 that is not present in SCF220 to specifically target SCF248 but not SCF220.
146 Due to the cleavage of exon 6 we chose a peptide on the membrane side of the cleavage
147 domain; thus, this mAb did not bind to the portion of SCF248-extracellular domain that is shed
148 into the circulation after cleavage(21). Flow cytometric analysis of ATCC cell lines that express
149 no SCF, only SCF220, or only SCF248 isoforms demonstrated that the mAb against this peptide
150 in exon 6 only binds to membrane associated SCF248 and not to SCF220 (Figure 3A). In
151 addition, Biacore surface plasmon resonance analysis of anti-SCF248 showed that this *mAb*
152 has an affinity to peptide of 4.5×10^{-9} M (4.5 nM; Figure 3B). Thus, these results demonstrate
153 that anti-SCF248 *mAb* is specific to SCF248 isoform and it binds its ligand with high affinity.

154 We hypothesized that antibody binding to surface SCF248 would promote the
155 internalization negating its ability to signal c-kit. To examine this, we used a pH sensitive
156 fluorescent tag (Phrodo red) coupled to our mAb where fluorescence is only observed when the
157 pH drops to below 6 in endosomes. SCF248 expressing cells treated with the labeled anti-
158 SCF248 antibody showed an increase in fluorescence starting at 5 minutes and continued to
159 increase by 60 minutes (Figure 3C,3D). In addition, cultured IPF patient-derived fibroblasts were
160 incubated with anti-SCF248 or control antibody coupled with the pH sensitive fluorescent tag
161 and showed a similar internalization at 15 minutes (Figure 3E). These results suggest that anti-
162 SCF248 mAb induce internalization of cell surface SCF248 protein into endosomes and
163 lysosomes allowing the clearance from the surface.

164 Previous studies that utilized specific expression of the different isoforms have
165 demonstrated that the erythropoiesis function of SCF-c-kit is due to SCF220 and not

166 SCF248(36). To determine if anti-SCF248 mAb altered erythropoiesis, mice were intravenously
167 administered a polyclonal rabbit anti-mouse antibody (250 mg/kg) that recognizes both SCF
168 isoforms or anti-SCF248 mAb (100 mg/kg) every other day. At day 8 the peripheral blood was
169 examined for levels of circulating hematopoietic cells, with a focus on reticulocytes that have
170 recently entered circulation from bone marrow. The data in Figure 3F illustrate that polyclonal
171 anti-SCF, but not anti-SCF248 mAb, caused a significant decrease in reticulocytes in the
172 peripheral blood. These results support previous studies and suggest that SCF220, but not
173 SCF248, is required for normal erythropoiesis(36).

174 Mast cell induced IPF patient-derived fibroblast activation is SCF248 dependent

175 Previous studies from our lab have demonstrated that fibroblasts upregulate SCF and
176 can activate mast cells(28) and studies examining tissue fibrosis suggest that mast cells play a
177 role in the progression and severity of the disease (1, 8, 11, 41, 68, 72). We examined whether
178 IPF lung fibroblasts activated mast cells and whether anti-SCF248 was effective at blocking
179 activation. We utilized the LAD2 mast cell line, which is SCF-dependent(40). SCF-dependent
180 LAD2 cells were layered onto normal or IPF lung fibroblasts for 24 hours in the presence of
181 control or anti-SCF248 antibodies. Anti-SCF248 significantly reduced COL1A1, COL3A1 and
182 FN1 transcript expression in co-cultured IPF lung fibroblasts vs. IgG treated cells with no
183 increase activation when layered onto normal fibroblasts (Figure 4A). When we used the anti-
184 SCF248 mAb for immunohistochemical analysis, abundant staining for SCF in IPF lung tissues
185 especially in the fibrotic tissue (Figure 4B) was observed compared to non-fibrotic lungs
186 samples from respiratory bronchiolitis-associated interstitial lung disease (RBILD) patients with
187 staining only detected in macrophage populations. Thus, blocking SCF248 has a functional
188 effect on fibrotic genes and it is highly expressed in areas of active remodeling in IPF disease.

189 Specific inhibition of the SCF248 isoform inhibits lung remodeling responses.

190 Our previous data using polyclonal antibodies that recognize all isoforms of SCF
191 demonstrated an attenuation of bleomycin-induced fibrosis(15), however the differential roles of
192 SCF220 and SCF248 are not known. To assess the role of SCF248 in lung fibrosis, anti-

193 SCF248 or control ab (20 mg/kg) were given by IP injection in bleomycin-exposed mice on d8
194 and d12 post-bleomycin treatment (fibrotic phase). Figure 5A illustrates that anti-SCF248
195 antibody treatment reduced the development of fibrosis and the consolidation of alveolar space.
196 Biochemical quantification of hydroxyproline from lung tissue indicated a significant decrease in
197 the anti-SCF248 vs. control antibody treated mice (Figure 5B). Transcriptomic analysis by qPCR
198 demonstrated a significant decrease in several pro-fibrotic transcripts, including *tgfb*, *ccl2*,
199 *col1a1*, *fn1*, *acta2*, and *SCF* itself (Figure 5C). Pulmonary function tests performed on Day 16
200 demonstrate that FEV₁₀₀ and FEF₂₅ were significantly reduced in the control IgG bleomycin mice
201 compared to naïve mice, whereas anti-SCF248 treated animals were not significantly different
202 from naïve mice (Figure 5D). Pulmonary pressure increases due to development of fibrosis and
203 was significantly ameliorated in the anti-SCF248 treated mice vs. control ab and further
204 appeared to fully recover to normal levels (dPpl; Figure 5D). Finally, c-kit⁺ mast cells,
205 eosinophils and ILC2 were significantly increased in the control IgG treated bleomycin mice but
206 not in the anti-SCF248 treated animals (Figure 5E). Together, these data demonstrate that
207 therapeutic targeting of SCF248 using a specific mAb attenuated the development and
208 progression of severe lung fibrosis.

209 Selective deletion of SCF in *col1a1* expressing cells attenuates Bleomycin-induced fibrosis.

210 Genetic proof-of-concept can be important to establish function of specific molecules during
211 disease. However, complete deletion of SCF is lethal having significant systemic consequences.
212 Therefore, we generated a mouse that lacks SCF in Collagen 1-positive cells, SCF^{fl/fl}-Col1-
213 CreERT2 mouse, when induced by tamoxifen treatment. Col1-Cre⁻ and Col1-Cre⁺ littermates
214 were given bleomycin intratracheally and treated with tamoxifen daily from days 6-12 post-
215 bleomycin to delete SCF from mesenchymal cells in the Cre⁺ mice. Histologic assessment at
216 demonstrated that the Col1-Cre⁺ mice showed markedly less remodeling and reduced
217 consolidation of the lungs vs. Col1-Cre⁻ littermate mice (Figure 6A). The bleomycin challenged
218 mice showed a significant decrease in *ccl2*, *col1a1* and *fn1* expression and a trending, but not
219 significant, reduction in *tgfb* and *acta2* expression in the Cre⁺ mice (Figure 6B). Hydroxyproline

220 quantification showed a significant decrease in tamoxifen treated Col1-Cre⁺ mice vs. Col1-Cre⁻
221 littermate control mice (Figure 6C). These results suggest that fibroblast-associated SCF
222 promotes lung remodeling *in vivo* and further supports with genetic proof-of-concept that
223 SCF248 may be an effective therapeutic target in lung fibrosis.

224 Discussion

225 The identification of novel therapeutic targets induced during tissue fibrosis will be
226 central to development of new reagents to block the progression of end-stage fibrotic diseases.
227 Previous studies have implicated SCF as a viable target during pulmonary fibrosis, primarily
228 using animal models (5, 15, 17, 18, 45, 72). However, the present studies link the
229 overexpression of SCF in patients with IPF, both by the examination of lung tissue microarray
230 data and in serum from peripheral blood of IPF patients. We have also been able to identify that
231 a primary isoform of SCF (SCF248, a.k.a. sSCF) is preferentially expressed in fibroblasts and
232 during induction of bleomycin-induced fibrosis. The overexpression of SCF248, compared to
233 SCF220, in both normal and IPF fibroblast is consistent with earlier results that reported
234 fibroblasts nearly exclusively express the longer isoform SCF248 containing exon 6 (3). By
235 specifically blocking the SCF248 isoform with a Mab that does not recognize SCF220 or
236 cleaved SCF-ECD, pro-fibrotic responses were significantly reduced in both *in vitro* co-culture
237 studies of IPF fibroblast with mast cells and *in vivo* after bleomycin induced lung remodeling.
238 Thus, during a fibroproliferative response, there would be a predominance of the longer SCF248
239 isoform that could be central to the progression of disease due to the expansion of
240 myofibroblasts. Experimentally this is supported in our studies using fibroblast- & myofibroblast-
241 specific genetic deletion and antibody neutralization (anti-SCF248) experiments that suggest
242 that SCF248 is a promising target during the progression of a pulmonary fibrotic response.

243 A primary role for SCF in fibrosis has been suggested to involve mast cell activation and
244 accumulation. Mast cells have been implicated in a number of fibrotic diseases including IPF,
245 kidney fibrosis, scleroderma, and others, where they have often been linked to the
246 overexpression of SCF in areas of active fibrosis (6, 19, 20, 34, 44, 63, 66). This link between
247 SCF expression and mast cells in fibrotic tissue is logical, since SCF has long been shown to be
248 involved in mast cell differentiation, survival and activation. In particular, mast cells release a
249 number of preformed mediators, such as histamine, chymase, and vasoactive amines, and
250 produce a number of cytokines, chemokines, and growth factors known to initiate and contribute

251 to chronic inflammation and fibrosis (7, 37, 42, 51, 52, 62). In the present studies,
252 transcriptomic analysis showed that SCF248 was ~20 times higher in the IPF patient lung
253 fibroblast compared to SCF220, while normal fibroblasts showed a similar predominance of
254 SCF248 expression. Indeed, blockade of fibroblast-associated SCF248 reduced mast cell
255 mediated expression of matrix transcripts by SCF248-rich IPF, but not normal, lung fibroblasts
256 in mast cell/ fibroblast co-culture studies. These results suggest that SCF248 is upregulated and
257 preferentially expressed in fibroblasts from IPF patients, where it may mediate fibroblast
258 activation through interaction with c-kit on cells in the microenvironment. In addition, IHC
259 staining of lung tissue demonstrated that non-fibrotic RBILD tissue had some SCF248 staining
260 in macrophage populations and no detectable structural cell staining compared to extensive
261 staining of remodeled areas of the lung of IPF patient tissue.

262 In addition to mast cells, other immune cell populations also express the SCF receptor,
263 c-kit, and may be activated by SCF and contribute to the progression of fibrotic disease.
264 Eosinophils have also been shown to express c-kit, and when activated by SCF, produce
265 profibrotic cytokines including TGF β and FGF as well as a number of other lipid mediators,
266 proteases, and chemokines(53). *In vitro* co-culture studies have suggested that SCF/c-Kit
267 mediated eosinophil activation can promote fibroblast activation and matrix production(16).
268 Further, our own data have previously implicated SCF in eosinophil activation and airway
269 remodeling in allergic asthma models (5) and other studies have linked eosinophils to severe
270 fibrotic disease progression (55, 64). More recently, another c-kit⁺ cell population, type 2 innate
271 lymphoid cells (ILC2), have been associated with disease progression in IPF, potentially through
272 the production of IL-5, IL-13 (26, 70, 71). The infiltration of the c-kit⁺ cells were impaired when
273 SCF248 was neutralized, including mast cells, eosinophils, and ILC2. While it is not clear to
274 what extent each of these populations contributes to the fibrotic responses in different end-stage
275 fibrotic diseases, the potential role for SCF in their activation and accumulation suggests a
276 strong correlation to disease severity.

277 The biology of SCF and c-kit activation is complex and not fully understood. It is known
278 that membrane associated SCF isoforms (both 220 and 248), as compared to cleaved, soluble
279 SCF-ECD, induce the most efficient activation of c-kit by allowing crosslinking and strong
280 signaling (3). Furthermore, studies have shown that the majority of cleaved soluble SCF is
281 monomeric in biologic solutions and therefore would not be able to activate c-kit efficiently (31).
282 Seminal studies found that SCF220 and SCF248 have biologically different functions, with
283 SCF220 providing the homeostatic functions of erythropoiesis and overall growth and health in
284 mice, whereas SCF248 did not alter those same functions but did affect mast cells and myeloid
285 cell populations (36). These differences provide fidelity in the system, where based upon
286 regulated expression in specific cell populations or tissue, these isoforms can provide targeted
287 function(s). The regulation of post-transcriptional modification has not been defined under
288 homeostatic or disease conditions; however, it is speculated that these modifications must be
289 tightly regulated. It is possible that fibroblasts preferentially produce the SCF248 isoform to
290 modulate immune cell activation during normal growth and repair processes. The presence of
291 exon 6 in the SCF248 isoform (that appears to be most closely associated with inflammatory
292 and fibrotic responses) would allow more efficient cleavage of SCF from the surface of the
293 expressing cells by the immune cell derived proteases, such as mast cell chymase (14). Thus,
294 the removal of SCF248 by this process would limit immune cell activation at the site of the
295 response (unless continuously expressed on the surface such as in fibrosis) and therefore
296 function to limit the ongoing inflammatory responses. Our previous data have demonstrated that
297 SCF248, but not SCF220, is upregulated on fibroblasts by inflammatory and pro-fibrotic
298 cytokines, providing a "feed forward" loop in tissue fibrosis (22). Likewise, SCF220, which
299 appears to provide a more membrane-stable isoform (without exon 6 cleavage sites), might be
300 more functional during critical homeostatic processes, such as erythropoiesis (36).

301 Our understanding of the function of the different SCF isoforms continues to be
302 incomplete due to a lack of appropriate reagents, especially those specific for SCF220, as well
303 as the ability to properly detect each isoform's biologic function under homeostasis and disease

304 conditions. Using novel genetic and antibody tools that have been generated to examine the
305 function of SCF248, we have identified a specific, non-redundant role for the SCF248 isoform in
306 lung remodeling using the bleomycin model. Together the data provided in these studies
307 demonstrate differential expression and disease relevance of the SCF248 isoform and suggest
308 that SCF248 may be an important therapeutic target in fibrotic lung diseases.

309

310

311 **Materials and Methods**

312 Study approval: Institutional Review Boards at the University of Michigan approved all
313 experiments with primary human cells and serum. All patients were consented prior to
314 inclusion in the studies described herein and all samples were de-identified prior to
315 utilization.

316 Ingenuity Pathway Analysis: Publicly available gene expression datasets (GSE24206) were
317 mined from NCBI's geo datasets database. Groups were defined as follows – IPF lung biopsies
318 (n=8) vs normal lungs (n=6). Gene expression values were extracted using NCBI's Geo2R
319 gene expression analysis tool and the expression data were uploaded onto ingenuity IPA
320 (QIAGEN Redwood City, www.qiagen.com/ingenuity). Ingenuity IPA was set to only consider
321 changes in gene expression of 1.5-fold or greater and $p \leq 0.05$. To generate KITLG interaction
322 network, Ingenuity's path-designer tool was utilized. Briefly, KITLG was added to the custom
323 pathway designer and Ingenuity was set to grow the pathway using known direct downstream
324 activation molecules (based on Ingenuity's knowledgebase). For transcription factor targets,
325 Ingenuity was set to grow the transcription factor network by only considering molecules known
326 to be direct downstream targets of the highlighted transcription factor (Based on Ingenuity's
327 knowledgebase). After the generation of a KITLG interaction network, gene expression datasets
328 from IPF lung biopsies relative to normal lung explant were overlaid and exported.

329 Mice: Female C57BL6 mice (6-8 weeks old), SCF^{fl/fl} mice and Col1-CreERT2 mice were
330 purchased from Jackson Laboratory (Bar Harbor, ME). The SCF^{fl/fl} mice were crossed with the
331 Col1-CreERT2 mice to generate SCF^{fl/fl}-Col1CreERT2 C57BL6 mice that can be treated with
332 tamoxifen (1mg/mouse Intraperitoneally) to activate Cre in cells expressing Col1 and deleting
333 SCF specifically from those cells only when treated with tamoxifen. All animal studies were
334 reviewed and approved by the University Committee on Use and Care of Animals at the
335 University of Michigan, an AAALAC accredited institution.

336 Bleomycin-induced pulmonary fibrosis- Mice were given bleomycin (Bleomycin, Hospira, Lake
337 Forest, IL) at a dose of 2.5 U/kg body weight as previously described as previously
338 described(15). Control mice received the same volume of sterile PBS only. Where indicated
339 mice were treated with monoclonal control or anti-SCF248 antibodies or given tamoxifen to
340 activate Cre in the SCF^{fl/fl}-Col1CreERT2 transgenic mice by intraperitoneal injection. After 16
341 days the animals were sacrificed, serum and lung tissue were harvested for histologic, mRNA
342 and protein analyses as described below.

343 Production and administration of anti-SCF248 monoclonal antibodies (Mab)- A peptide from
344 exon 6 of SCF248 was generated and used as an immunogen in mice by a contract research
345 organization (GenScript, Inc., Newark, N.J.) and hybridomas were made after several rounds of
346 boosting immune responses. Twelve different hybridoma clones were identified as producing
347 SCF248 peptide specific antibody and further characterized for binding and function. A primary
348 antibody with high affinity, was identified, further expanded, and purified to generate endotoxin
349 free reagent for use in our analyses. The Mab is of the IgG1 isotype class. Since exon 6 is
350 completely conserved across mammalian species, the monoclonal antibody is fully cross-
351 reactive and binds to mouse and human SCF248. Antibody suspended in PBS was
352 administered into mice by intraperitoneal injection at a concentration of 20 mg/kg with a control
353 isotype matched control monoclonal antibody given at the same concentration.

354 Flow cytometric analysis- Differential binding of anti-SCF248 Mab to SCF isoforms was
355 determined using ATCC cell lines that specific expressed either human SCF220 or SCF248 and
356 flow cytometry analysis using SCF248 Mab directly labeled with Alexis Cy5 fluorescent marker.
357 Briefly, cells were stained with Alexis Cy5 conjugated anti-SCF248 Mab for 15 minutes and
358 analyzed using a BD LSRII flow cytometer (BD biosciences).

359 Lung Flow cytometry-The lungs were removed, and single cells were isolated by
360 enzymatic digestion with 1 mg/ml collagenase A (Roche, Indianapolis, IN) and 20 U/ml DNaseI
361 (Sigma, St. Louis, MO) in RPMI 1640 containing 10% FCS. Tissues were further dispersed
362 through an 18-gauge needle (10-ml syringe), RBCs were lysed and samples were filtered

363 through 100- μ m nylon mesh twice. Cells were resuspended in PBS and live cells were identified
364 using LIVE/DEAD Fixable Yellow Dead Cell Stain kit (Thermo Fisher Scientific, Waltham, MA),
365 then washed and resuspended in PBS with 1% FCS and Fc receptors were blocked with
366 purified anti-CD16/ 32 (clone 93; BioLegend, San Diego, CA). Surface markers were identified
367 using Abs (clones) against the following antigens, all from BioLegend: anti-Gr-1 (RB6- 8C5),
368 B220 (RA3-6B2), CD3 (145-2C11), Ter119 (Ter-119), CD11b (M1/70), CD25 (PC61), CD45 (30-
369 F11), CD127 (SB/199), ST2 (DIH9), c-KIT (2B8) and CD90 (30-H12). SiglecF (E50-2440) was
370 purchased from BD Biosciences (San Jose, CA). For innate lymphoid cell staining, lineage
371 markers were anti-CD3, CD11b, B220, Gr-1, and TER119. ILC2: Lin-CD45+CD25+CD90+ST2+
372 c-Kit +CD127+. Eosinophils: SSC^hCD45+11b+SiglecF+. Mast cells:
373 CD45+CD11b+cKIT+Fc ϵ R1+. Data was collected in NovoCyte flow cytometer (ACEA
374 Bioscience, Inc. San Diego, California). Data analysis was performed using FlowJo software
375 (Tree Star, Oregon).

376 Human lung fibroblast and mast cell co-cultures- IPF lung biopsies were obtained from
377 consented patients at the University of Michigan medical Center. Normal non-fibrotic
378 explanted lungs were obtained from rejected donor lungs. Lung fibroblasts were
379 generated and cultured as previously described(35). For *in vitro* studies, cells were
380 transferred into 6 well plates and used with or without co-culture with SCF-dependent LAD2
381 human mast cells, which were generously supplied by Dr. Dean Metcalfe (NIAID, NIH,
382 Bethesda, MD) under an MTA agreement. In experiments where the role of SCF248 was
383 examined in the Fibroblast:LAD2 co-cultures, anti-SCF248 or control Mab (20 ug/ml) was pre-
384 incubated with the fibroblasts for 15 minutes prior to adding the LAD2 mast cells, followed by an
385 overnight (18 hr) co-culture period.

386 RNA Isolation and Quantitative PCR- RNA were extracted with TRIzol (Invitrogen) following
387 manufacturers protocol, and total RNA were reverse transcribed to cDNA to determine gene
388 expression using Taqman gene expression primer/probe sets and SYBR for SCF220 and
389 SCF248 transcripts as described (31). Detection was performed in ABI 7500 Real-time PCR

390 system. Gene expression was calculated using $\Delta\Delta\text{Ct}$ method and normalized with 18s control
391 expression for all other genes.

392 Hydroxyproline assay

393 Lung hydroxyproline content was measured in whole lung homogenates as previously described
394 (27). The results were expressed as μg of hydroxyproline per left lobe of the lung.

395 Statistical Analysis- Data were analyzed by Prism6 (GraphPad). Data presented are mean
396 values \pm SEM. Comparison of two groups was performed in unpaired, two-tailed, Student's *t*-
397 test. Comparison of three or more groups was analyzed by ANOVA with Tukey's post-tests.
398 Significance was indicated at the level of *: $p < 0.05$ unless otherwise indicated.

636 **Figure legends:**

637 *Figure 1: SCF is highly expressed in IPF lungs and blood.*

638 (A) Ingenuity IPA was utilized to generate KIT-KITLG interaction and transcriptional activation
639 network. The resulting network was then overlaid with gene expression datasets from IPF lung
640 biopsies relative to normal lung explants (GSE24206). KIT activated kinases and transcription
641 factors are shown in large font and direct downstream targets for the activated transcription
642 factors are shown in small fonts. Solid arrowheads indicated activation (A) or expression (E).
643 Significantly upregulated (≥ 1.5 fold change and $p \leq 0.05$) and downregulated (≥ -1.5 fold
644 change and $p \leq 0.05$) are depicted in red and green color, respectively. (B) Serum from normal
645 (n=9) or patients newly diagnosed with IPF by HRCT assessment (n=41) were measured for
646 SCF levels using a specific ELISA (R&D Systems, Rochester, MN). Levels of SCF were
647 measured in serum collected after diagnosis.

648

649 *Figure 2: SCF248 is highly expressed by IPF lung fibroblasts and in fibrotic mouse lungs.*

650 (A) RNA was extracted from Normal and IPF lung fibroblasts and subject to quantitative PCR
651 analyses using SCF220 and SCF248 specific primer sets. Data are expressed as fold change of
652 SCF248 over SCF220 to compare relative levels between the isoforms in patient-derived
653 fibroblast cell line. Shown is the mean \pm SEM of 3 cell lines. (B) Full length SCF, SCF220 and
654 SCF248 transcript expression levels in lungs of 16-day bleomycin treated B6 mice expressed as
655 fold increase over control untreated mice. Data represents mean \pm SE from 5 mice/group.

656

657 *Figure 3: Characterization of anti-SCF248 Mab.*

658 (A) Using ATCC cell lines CRL-2452, CRL-2453, and CRL-2454 that express no SCF, SCF220,
659 or SCF248, respectively, the monoclonal antibody was used for Flow cytometry binding assays
660 to demonstrate specificity. (B) Monoclonal antibody generated to a peptide from exon 6 of
661 SCF248 was subjected to Biacore surface plasmon resonance (SPR) analysis to the specific
662 peptide. The data generated dose response curves that were assessed to have a fast on rate

663 and a slow off rate with a 4.5 nM KD binding. (C) Image Flow Cytometry photos of ATCC
664 SCF248 expressing cells incubated for 5 or 60 minutes with anti-SCF248 or control IgG1 mAb
665 couple with phrodo-red pH sensitive fluorescent dye. (D) Mean fluorescent intensity (MFI) of
666 ATCC SCF248 expressing cells incubated with control or anti-SCF248 mAb coupled with
667 phrodo-red dye over time to demonstrate internalization. (E) IPF patient lung fibroblast cultures
668 incubated fro 15 minutes with control or Anti-SCF248 mAb coupled with phrodo-red dye
669 showing internalization only in the anti-SCF48 mAb incubated cells. (F) Naïve Balb/c/J mice
670 were injected intravenous with either control IgG (250 mg/kg), polyclonal anti-SCF (250 mg/kg),
671 or anti-SCF248 monoclonal ab (100 mg/kg) on day 0, 2, 4, and 6. The peripheral blood was
672 assessed for reticulocyte numbers on day 8 as an indication of reduced erythropoiesis as a % of
673 total cells. Data represents the mean \pm SE from 8 mice/group.

674

675 *Figure 4: Monoclonal Ab to SCF248 blocks LAD2 mast cell induced myofibroblast activation.*

676 (A) Fibroblast cell lines from either non-fibrotic ("normal") or IPF fibrotic lung biopsies were
677 plated in 48-well plates to confluent monolayers. Control or anti-SCF248 monoclonal antibodies
678 (10 ug/ml) were added 30 minutes prior to layering of 2×10^5 LAD2 mast cells onto the
679 monolayers for 24 hrs and assessed for increased matrix gene expression compared to control
680 fibroblasts with no mast cells added to the culture. Data represents mean \pm SE.

681 * $P < 0.05$ compared to the control ab treated cells. (B) Immunohistochemistry using anti SCF248
682 monoclonal antibody on tissue biopsy sections from 2 patients with IPF or RBILD. IgG control
683 antibodies were used in IPF patient sections and did not show any non-specific staining. A
684 secondary alkaline phosphatase antibody was used to visualize the staining.

685

686 *Figure 5: Therapeutically targeting of SCF248 using an isoform specific Mab significantly*
687 *ameliorated bleomycin induced lung fibrosis.*

688 (A) Representative histology from 10 week old B6 mice 17 days after exposure to intratracheal
689 bleomycin and treated with control or anti-SCF248 monoclonal antibody (20 mg/kg) on day 8

690 and 12 after the bleomycin challenge. (B) The single left lobe was harvested from the normal
691 and bleomycin treated animals and assessed for hydroxyproline. (C) The upper right lobe of the
692 lung was used for isolation of mRNA and assessed for expression of the indicated genes by RT-
693 PCR. (D) Mice were examined 17 days post-bleomycin treatment for pulmonary lung function
694 using anesthetized and ventilated animals with bleomycin treated animals given control or anti-
695 SCF248 mAb on days 8 and 12 post-bleomycin instillation. (E) Mice were treated with IgG
696 control or anti-SCF248 mAb on days 8 and 12 post-bleomycin instillation and examined for c-
697 kit+ cell infiltration by flow cytometry on day 17. Data represents the mean \pm SE from 6-8
698 mice/group.

699

700 *Figure 6: SCF248 deletion in collagen 1 expressing cells significantly reduced bleomycin*
701 *induced lung fibrosis.*

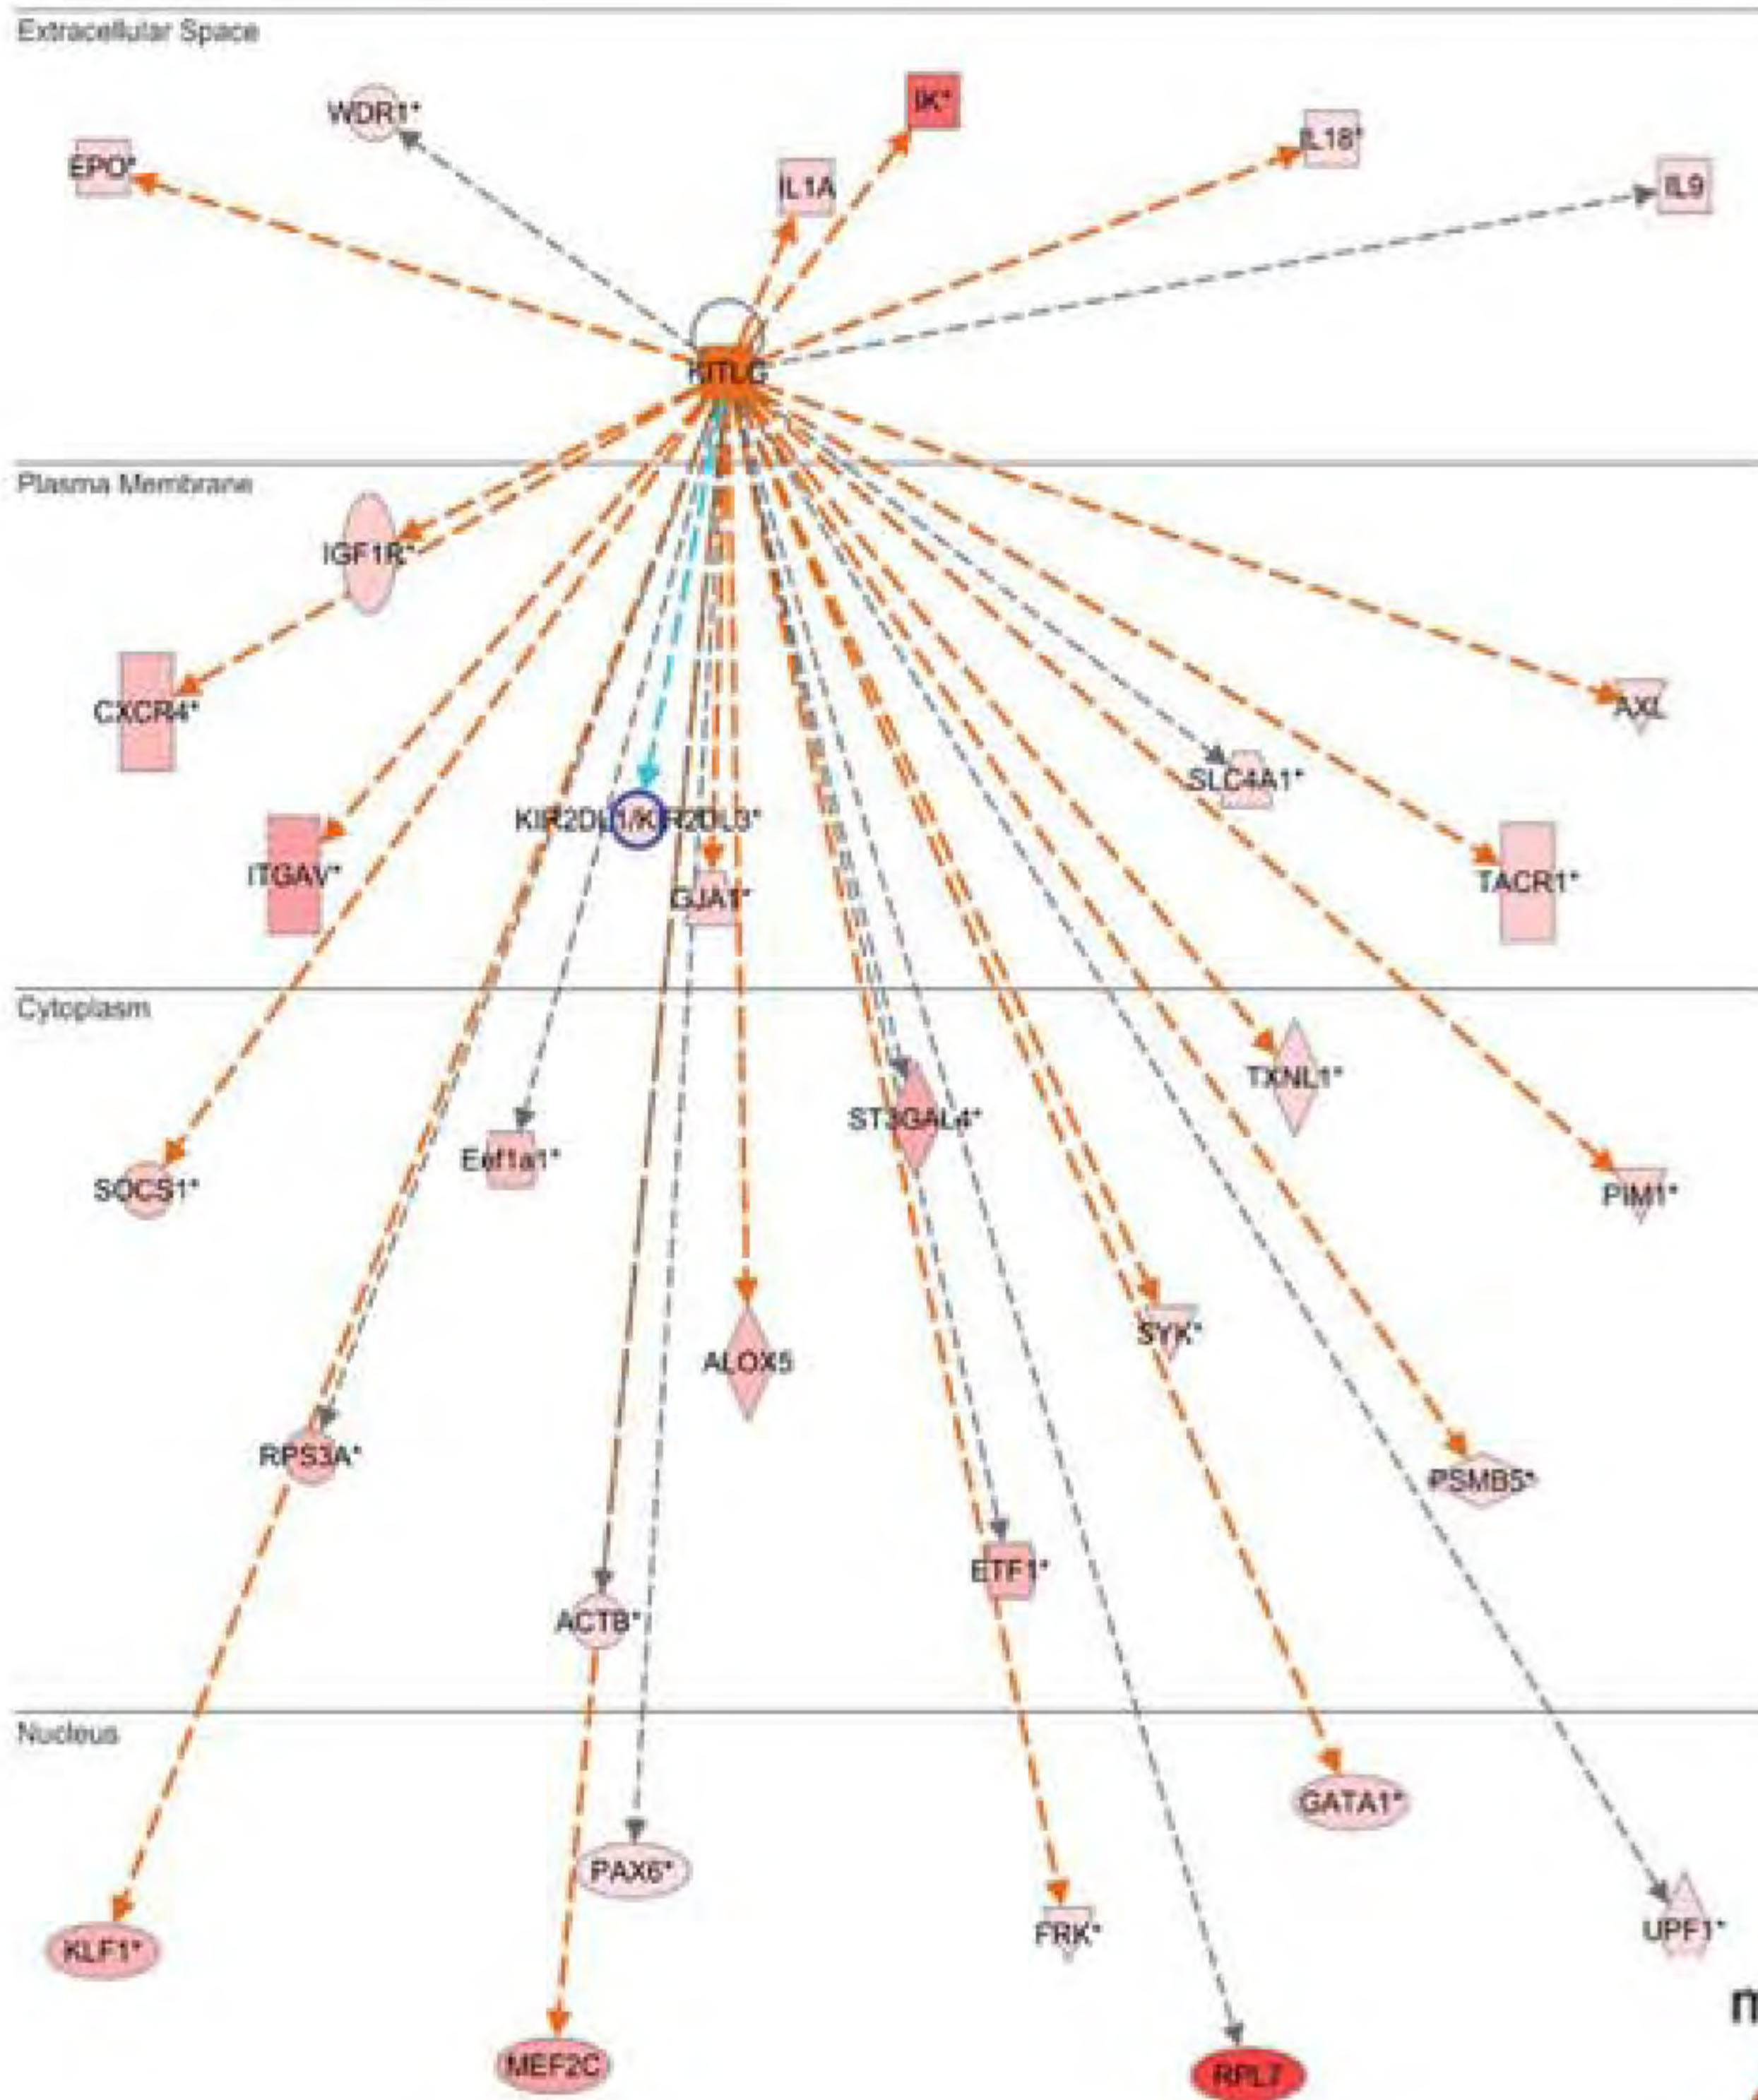

702 (A) Representative histology from lung bleomycin treated 10-12 week old B6 SCF^{fl/fl} Col1a-Cre-
703 ERT mice exposed with tamoxifen (days 6-12 after bleomycin) to delete SCF expression in
704 mesenchymal cells (myofibroblasts). Animals were harvested on day 17 after bleomycin
705 instillation. (B) The upper right lobe of the lungs from day 17 bleomycin treated mice were
706 processed for mRNA analysis by RT-PCR and genes expressed as fold increased over control
707 non-bleomycin exposed mice. (C) Hydroxyproline analysis was performed on the single left
708 lobe of the animals and expressed as total hydroxyproline in the left lobe. Data represents mean
709 \pm SE from 6-7 mice/group.
